

Here's a detailed theory overview for **Session 4: Service Operation**, structured around its key themes and supported by the latest ITIL best practices:

☒ **Balancing Conflicting Goals**

Service Operation must strike a balance between **service quality (reliability, availability)** and **operational costs**. This trade-off requires continuous optimization—high availability comes at a price, while cost reduction must not compromise service levels. It's about finding the optimal point between stability and spend (en.wikibooks.org).

☒ **Event Management**

Event Management continuously monitors the IT environment, **filtering notifications** (informational, warning, exception) to identify actionable issues. Appropriate responses—such as logging incidents or notifying operators—are triggered based on severity (en.wikipedia.org). It supports proactive management by catching problems before they escalate.

☒ **Incident Management**

An **incident** is any unplanned service interruption or degradation. Incident Management aims to **restore normal service quickly**, minimizing

business impact. It handles each phase: detection, logging, prioritization, diagnosis, escalation, resolution, and closure (fynd.academy).

☒ Problem Management

Problems are **underlying causes** of one or more incidents. Problem Management seeks to **identify root causes**, usually via root-cause analysis, implement workarounds, and put permanent fixes or changes in place. It includes **reactive** (responding to incidents) and **proactive** (identifying trends) approaches, and maintains a Known Error Database (KEDB) (fynd.academy).

☒ Request Fulfillment

Also known as **service request management**, this process addresses standard user requests—like password resets, information queries, or simple changes—through standardized workflows and pre-approved models .

☒ Access Management

Access Management ensures only **authorized users gain access** to services while preventing unauthorized access, enforcing security policies created by Information Security Management (wiki.en.it-processmaps.com).

☒ Asset Management

IT Asset Management inventories and tracks IT assets (hardware, software, licenses), ensuring they are well-maintained and used efficiently throughout their lifecycle ([reddit.com](#)).

☒ Service Desk

The **Service Desk** acts as the **single point of contact** between users and IT, managing incident logging, request tracking, escalation, communication, and reporting. It fulfills both reactive (incident handling) and proactive (user guidance) roles ([fynd.academy](#)).

☒ Technical & Application Management

- **Technical Management** provides deep infrastructure expertise in areas like networking and data centers, supporting management and stability of systems ([reddit.com](#)).
- **Application Management** covers the full **lifecycle of software applications**, focusing on availability, error handling, and performance tuning ([fynd.academy](#)).

⌘ Key Roles & Responsibilities

Role	Responsibility
Incident Manager / Major Incident Manager	Oversees incident lifecycles and major incident resolution procedures (manageengine.com).
Problem Manager	Manages root cause activities, KEDB updates, and trend analysis .
Service Desk Analyst / Manager	Handles user interactions, incident/request logging, first-level support, escalations .
Technical Lead / Application Manager	Provides second/third-level support for complex or specialized IT issues .
IT Operations Manager	Manages daily operations, facilities, monitoring, and automation .

This session captures the **essence of operational excellence**: delivering stable, secure, and efficient IT services through structured processes, clear roles, and continuous optimization. Let me know when you're ready for the accompanying **40-MCQ set** or any deep dives!
